assigning a grouping hierarchy for the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and

calculating an orientation and position of the child object relative to the first virtual object.

assigning an origin on the first virtual object around which the second virtual object can rotate; and

assigning a three-dimensional constraint of motion to the second virtual object that constrains how the second virtual object can rotate with respect to the first virtual object.

107. (Amended) The medium of claim 102, further comprising specifying a minimum angle and a maximum angle that the second virtual object can rotate with respect to the origin.

108. (Amended) The medium of claim 102, further comprising assigning an attributes to the grouped object, wherein the attribute is texture, color, normal direction, maximum rotation angle, or minimum rotation angle.

## REMARKS

Claims 1-46, 48-94, and 97-108 are pending. In the Office Action dated November 11, 2000, the Examiner rejected all claims under 35 U.S.C. 251 as being an improper recapture of subject matter surrendered in the application for the patent upon which the present reissue is based. Applicants respectfully traverse the Examiner's rejection for reasons set forth below.

Regarding the rejection of claims 1-9, Applicants contend the Examiner's interpretation of the reissue statute is contrary to that of the Federal Circuit. In Clement, the reissue application included claims 1-18, which corresponded to claims 1-18 of the original patent, and claims 49-52, which were admittedly broader than the original patent's claims. While the Federal Circuit held that claims 49-52 had been impermissibly broadened in violation of the recapture rule, the Court nevertheless held that original claims 1-18 were allowable despite the Examiner's attempts to invalidate them for a defective declaration (i.e., for failure to properly state an error warranting reissue). The Court noted that "because under 35 U.S.C. § 252 (1994) the surrender of the '179 patent does not take effect until the reissue patent issues, 'original claims 1-18 [not subject to the

recapture rule] continue to exist with their normal presumption of validity,' unaffected by the examiner's rejection based on the allegedly defective declaration." <sup>1</sup> Thus, Applicants contend that unless the Examiner is able to find a substantive reason for rejecting claims 1-9 (e.g., new prior art), claims 1-9 should be allowed.

During the prosecution of U.S. Patent 5,559,995, the claims were amended in a response dated April 1, 1996. Prior to the amendment, the Examiner rejected all claims based on different combinations of Wexelblat, et al. (U.S. Patent No. 5,021,976), Richburg (U.S. Patent No. 5,159,687), and Fisher, et al. ("Virtual Environment Display System").

In the April 1, 1996 response, Applicants noted that the combination of cited art failed to teach or disclose a "grouping means" as recited in claim 1 and claim 7 (see top of pages 10 and 13 of April 1, 1996, response). Applicants contend that a feature similar to the "grouping means" is included in the pending claims, as highlighted below.

In general, Applicants contend that claims 10-108 do not violate the recapture rule because the features germane to the prior art rejection (i.e., the "grouping means") have been included and because additional features have included which material change the scope of the claims such that they materially differ from the coverage of the original claims 1-10. Applicants note that the original application only included apparatus claims, and, as the Examiner noted, Applicants are entitled to include method and computer medium claims as part of the reissue application. Applicants note that method and computer medium claims inherently require different language than apparatus claims. Thus, Applicants contend that the Examiner's apparent requirement that the exact wording of the original claims be copied verbatim *in toto* into any new claims is unworkable. Below, Applicants have attempted to succinctly highlight which features have been incorporated into the new reissue application claims relative to the amendments made to the claims in the original application.

Regarding claims 46-56 and 69-83, Applicants request that the Examiner compare claims 46 and 69 with claim 1 from the reissue application (see tables below). Applicants contend that claim 46 includes all features germane to the prior art rejection of claim 1. Applicants further

<sup>&</sup>lt;sup>1</sup> In Re Clement, 45 USPQ.2d 1161, 1167 (Fed. Cir. 1997)

note that the scope of claim 46 is different than claim 1 because claim 46 recites "assigning a grouping hierarchy for the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and calculating an orientation and position of the child object relative to the first virtual object."

Claim from original patent (with additions underlined)	Claim in present reissue application (emphasis added)		
1. An apparatus for creating a virtual world	46. (Amended) A memory media comprising		
data base, comprising:	program instructions for creating a data base		
	representing a virtual world, wherein the		
	program instructions are executable to		
	implement:		
receiving means for receiving first, second and	receiving a plurality of polygon representations		
third polygon representations of respective	of a plurality of virtual objects including a first		
first, second and third virtual objects in a	virtual object, a second virtual object, and a		
virtual world;	third virtual object;		
selecting means, coupled to said receiving	selecting the first and second virtual objects		
means, for selecting a first edge of said first	from said plurality of polygon representations		
virtual object and for selecting a second edge	of virtual objects using edges of the virtual		
of said second virtual object; and	objects;		
grouping means, coupled to the receiving	grouping the first and second virtual objects		
means and the selecting means, for grouping	into a three-dimensional grouped object		
said first and second virtual objects in the	represented by at least one of the following:		
virtual world into a grouped object comprising	a three-dimensional and rotatable		
said first and second virtual objects joined at	wireframe object, and		
an intersection of the first and second edges,	a three-dimensional and rotatable		
the grouped object represented by at least one	polygon object;		
of a three-dimensional and rotatable wireframe	assigning a grouping hierarchy for the first and		

object and a three-dimensional and rotatable	second virtual objects, wherein the second	
sweep polygon.	virtual object is assigned as the child of the	
	first virtual object; and	
	calculating an orientation and position	
	of the child object relative to the first virtual	
	object.	

Applicants further highlight that dependent claims 47-57 recited additional features not addressed in claim 1, and thus differ in scope sufficiently to avoid the recapture rule. For example claim 53 recites "assigning color values to the grouped object, wherein each virtual object in the grouped object inherits the color values." Applicants contend that these additional features materially change the scope of claims 47-57 relative to the original claims.

Claim from original patent	Claim in present reissue application	
(with additions underlined)		
1. An apparatus for creating a virtual world	69. (Amended) A method for creating a data	
data base, comprising:	base representing a virtual world, the method	
	comprising:	
receiving means for receiving first, second and	receiving a plurality of polygon representations	
third polygon representations of respective	of virtual objects, wherein the plurality of	
first, second and third virtual objects in a	polygon representations include a first, a	
virtual world;	second, and a third representation of respective	
	first, second, and third virtual objects, wherein	
	the virtual objects have edges;	
selecting means, coupled to said receiving	selecting first and second virtual objects using	
means, for selecting a first edge of said first	the edges from said plurality of polygon	
virtual object and for selecting a second edge	e representations of virtual objects;	
of said second virtual object; and		
grouping means, coupled to the receiving	grouping the first and second virtual objects	
means and the selecting means, for grouping	ng into a grouped object comprising	
said first and second virtual objects in the	combination of the first and second virtual	

virtual world into a grouped object comprising	objects, wherein the first and second virtual	
said first and second virtual objects joined at	objects intersect; and	
an intersection of the first and second edges,		
the grouped object represented by at least one	representing the grouped object by at least one	
of a three-dimensional and rotatable wireframe	of the following:	
object and a three-dimensional and rotatable	a three-dimensional and rotatable	
sweep polygon.	wireframe object, and	
	a three-dimensional and rotatable	
	sweep polygon object.	

Applicants further highlight that dependent claims 70-83 recited additional features not addressed in claim 1, and thus differ in scope sufficiently to avoid the recapture rule. For example claim 70 recites "assigning a grouping hierarchy for the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and calculating an orientation and position of the child object relative to the first virtual object."

Regarding claims 84-94, Applicants contend that claims 84-94 includes all of the features germane to the prior art rejection based on Wexelblat, et al. (U.S. Patent 5,021,976) and Fisher, et al ("Virtual Environment Display System), as illustrated in the table below. Applicants also note that additional features are recited in claim 84 that are not cited in claim 1, e.g., "assign a grouping hierarchy to the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and calculate an orientation and position of the child object relative to the first virtual object." Applicants contend that with these additional features, claim 84 is not an attempt to recapture subject matter forfeited during prosecution, but rather an attempt to claim a different aspect of the invention. Applicants contend that this is permissible since this reissue application with filed within the two year statutory timeframe for broadening reissues. Applicants content that requiring **verbatim** every word from the previous claim is an overly harsh interpretation of the recapture rule. Applicants contend that this interpretation defies the clear language and intent of the reissue statute, as interpreted by the

courts, which have stated that the reissue statute and recapture rule should be applied in an equitable manner.<sup>2</sup>

Claim from original patent (with additions underlined)	Claim in present reissue application		
1. An apparatus for creating a virtual world	84. (Amended) A computer program for		
data base, comprising:	creating a virtual world data base, wherein said		
	computer program is embodied on computer-		
	readable media and comprises instructions		
	configured to:		
receiving means for receiving first, second and	read polygon representations of a plurality of		
third polygon representations of respective	virtual objects, including a first virtual object, a		
first, second and third virtual objects in a	second virtual object, and a third virtual object;		
virtual world;			
selecting means, coupled to said receiving	select the first virtual object and the second		
means, for selecting a first edge of said first	virtual object from said plurality of virtual		
virtual object and for selecting a second edge	e objects;		
of said second virtual object; and			
	assign attributes to the first and second virtual		
	objects;		
grouping means, coupled to the receiving	g group said first and second virtual objects into		
means and the selecting means, for grouping	g a grouped object, wherein said first and second		
said first and second virtual objects in the	e virtual objects intersect;		
virtual world into a grouped object comprising			
said first and second virtual objects joined at			
an intersection of the first and second edges,			
the grouped object represented by at least one	e represent the grouped object by at least one of		
of <u>a three-dimensional and rotatable</u> wireframe	the following:		
object and a three-dimensional and rotatable	a three-dimensional and rotatable		
sweep polygon.	wireframe object, and		
	a three-dimensional and rotatable		

<sup>&</sup>lt;sup>2</sup> See Ball Corp. v. U.S., 221 USPQ 289, 296 (Fed. Cir. 1984).

· I	
assign a groupin	g hierarchy to the first and
second virtual of	bjects, wherein the second
virtual object is	assigned as the child of the
first virtual object	ct; and
calculate an ori	ientation and position of the
child object relat	tive to the first virtual object.

Regarding claims 97-101, Applicants respectfully request that the Examiner compare claim 97 of this reissue application with claim 8 of the original patent (see table below). Applicants contend that claim 95 has all of the features germane to the prior art rejection that were added to claim 1 during the prosecution of the original patent, including the "means" language referred to by the Examiner. Applicants contend that the changes to the rendering means were clearly not to overcome the prior art, but rather for grammatical reasons. Since the rendering means was not narrowed in response to the prior art, the recapture rule does not apply to this element. Thus Applicants contend that claims 97-101 do not violate the recapture rule.

Claim from original patent	Claim in present reissue application
(with additions underlined) 8. An apparatus for creating a virtual world comprising:	97. (Amended) An apparatus for creating a virtual world data base, comprising:
receiving means for receiving <u>first</u> , <u>second and</u> third polygon representations of <u>respective</u> first, <u>second and third virtual</u> objects in a virtual world;	a receiving means for receiving first and second polygon representations of respective first and second virtual objects in a virtual world;
selecting means, coupled to said receiving means, for selecting a first edge of a first virtual object and for selecting a second edge of a second virtual object; and	a selecting means coupled to said receiving means and configured to select said first and second virtual objects by selecting one edge from each of said first and second virtual objects;

a grouping means, coupled to the receiving means and the selecting means, for grouping said first and second virtual objects in the virtual world into a grouped object comprising said first and second virtual objects joined at an intersection of the first and second edges, the grouped object represented by at least one of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable sweep polygon;  attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object of the first virtual object is calculated relative to the first virtual object is assigned as a child object of the first virtual object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  a grouping means coupled to said grouping means is configured to groups and first and second virtual object is and second virtual object is and attribute assigning means coupled to said grouping means, wherein said assigning means soupled to grouping means and selecting means is configured to groups and three-dimensional and rotatable wireframe object in and a three-dimensional and rotatable wireframe object and at three-dimensional and rotatable polygon object; wherein said assigning means is configured to assign an attribute assigning means coupled to said grouping means, wherein said assigning means is configured to grouping means coupled to said grouping means, wherein said assigning means for assigning an attribute assigning means for assigning a a child object, wherein said attribute assigning means further comprises:  a norigin assigning means for assigning an origin on the first virtual object can rotate, wherein said third v			
said first and second virtual objects in the virtual world into a grouped object comprising said first and second virtual objects joined at an intersection of the first and second edges, the grouped object represented by at least one of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable sweep polygon;  attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means is configured to assign an attribute to the first and second virtual objects, the attribute assigning means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a mans for assigning means for assigning a a constraint assigning means for assigning an origin and a constraint assigning means for assigning means for assigning means for assigning means for assigning and a constraint assigning means for assigning and a constraint assigning means for assigning means for assigning means for assigning means for assigning and a constraint assigning means for assigning means for assigning means for assigning and a constraint assigning means for assigning and a constraint assigning means for assigning and a constraint assigning means f	grouping means, coupled to the receiving	a grouping means coupled to said receiving	
virtual world into a grouped object comprising said first and second virtual objects joined at an intersection of the first and second edges, the grouped object represented by at least one of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable wireframe object; and attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  an attribute assigning means coupled to said grouping means, wherein said assigning means is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  constraint assigning means for assigning a constraint assigning means for assigning a constraint assigning means for assigning a constraint assigning means for assigning an origin on the first virtual object can rotate, wherein said third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and	means and the selecting means, for grouping	means and selecting means, wherein said	
object, wherein the grouped object is represented by at least one of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable wireframe object; and attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object is assigned as a child object of the first virtual object; and origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and constraint assigning means for assigning a norigin on the first virtual object can rotate; and constraint assigning means for assigning a norigin on the second virtual object around which the third virtual object can rotate; and constraint assigning means for assigning a norigin on the first virtual object around which the third virtual object can rotate; and constraint assigning means for assigning a norigin on the first virtual object around which the third virtual object can rotate; and constraint assigning means for assigning and a constraint assigning means for assigning and objects; and a constraint assigning means for assigning and objects; and a constraint assigning means for assigning and objects and a constraint assigning means for assigning and ob	said first and second virtual objects in the	grouping means is configured to group said	
an intersection of the first and second edges, the grouped object represented by at least one of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable sweep polygon;  attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is massigned as a child object of the first virtual object and an orientation and a position of the child object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a constraint assigning means for overtual object; and  an attribute assigning means coupled to said grouping means, wherein said assigning means is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy to the first and second virtual object is assigned as a child object of the first virtual object of the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  an origin assigning means for assigning an origin on the first virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and	virtual world into a grouped object comprising	first and second virtual objects into a groupe	
the grouped object represented by at least one of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable sweep polygon;  attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object, and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a constraint assigning means for aconstraint assigning means for assigning a constraint assigning means for aconstraint assigning mea	said first and second virtual objects joined at	object, wherein the grouped object is	
of a three-dimensional and rotatable wireframe object and a three-dimensional and rotatable sweep polygon;  attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a  and a three dimensional and rotatable polygon object; and  an attribute assigning means coupled to said grouping means, wherein said assigning means is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means for assigning a grouping hierarchy to the first and second virtual object, wherein the second virtual object is assigned as a child object of the first virtual object of the first virtual object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  constraint assigning means for assigning a a constraint assigning means for	an intersection of the first and second edges,	represented by at least one of a three-	
object; and  objec	the grouped object represented by at least one	dimensional and rotatable wireframe object	
attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a a constraint assigning means for assigning a a constraint assigning means for assigning an origin and an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  constraint assigning means for assigning an and a constraint assigning means for	of a three-dimensional and rotatable wireframe	and a three dimensional and rotatable polygon	
attribute assigning means, coupled to the grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object swherein the second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  an attribute assigning means coupled to said grouping means, wherein said assigning means is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy to the first and second virtual object is achild object of the first virtual object of the first virtual object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; wherein said attribute assigning means for assigning means for assigning means for assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and  constraint assigning means for assigning a a constraint assigning means for	object and a three-dimensional and rotatable	object; and	
grouping means, for assigning an attribute to the first and second edges of the first and second virtual objects, the attribute assigning means including:  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a  grouping means, wherein said assigning means is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy to the first and second virtual object, wherein the second virtual object of the first virtual object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  an origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  constraint assigning means for assigning a a constraint assigning means for	sweep polygon;		
the first and second edges of the first and second virtual objects, the attribute assigning means including:  is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy to the first and second virtual object is assigned as a child object of the first virtual object of the first virtual object is calculated relative to the first virtual object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  origin assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and  constraint assigning means for	attribute assigning means, coupled to the	an attribute assigning means coupled to said	
second virtual objects, the attribute assigning means including:  and second virtual objects, wherein the attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object can rotate; and  constraint assigning means for assigning a a constraint assigning means for assigning a an origin assigning means for assigning a an origin assigning means for assigning an origin an origin on the first virtual object can rotate; and  and second virtual objects, wherein the attribute assigning a prouping hierarchy to the first and second virtual object is assigned as a child object of the first virtual object of the first virtual object is calculated relative to the first virtual object, wherein said attribute assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and  constraint assigning means for assigning a a constraint assigning means for	grouping means, for assigning an attribute to	grouping means, wherein said assigning means	
means including:  attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy for the first and second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  attribute assigning means comprises  a hierarchy means for assigning a grouping hierarchy to the first and second virtual object is assigned as a child object of the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  an origin assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and  constraint assigning means for assigning a a constraint assigning means for	the first and second edges of the first and	is configured to assign an attribute to the first	
hierarchy means for assigning a grouping hierarchy for the first and second virtual objects wherein the second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and  origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  a hierarchy means for assigning a grouping hierarchy to the first and second virtual object is assigned as a child object of the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  an origin assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and  constraint assigning means for	second virtual objects, the attribute assigning	and second virtual objects, wherein the	
hierarchy means for assigning a grouping hierarchy for the first and second virtual objects wherein the second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and origin assigning means for assigning an origin on the first virtual object around which the third virtual object can rotate; and  hierarchy to the first and second virtual object is assigned as a child object of the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  an origin assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and  constraint assigning means for  a constraint assigning means for	means including:	attribute assigning means comprises	
constraint assigning means for assigning <u>a</u> a constraint assigning means for	hierarchy for the first and second virtual objects wherein the second virtual object is assigned as a child object of the first virtual object and an orientation and a position of the child object is calculated relative to the first virtual object; and origin assigning means for assigning an origin on the first virtual object around which the	hierarchy to the first and second virtual objects, wherein the second virtual object is assigned as a child object of the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:  an origin assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said	
		objects; and	
three-dimensional constraint of motion to the assigning a three-dimensional constraint of	constraint assigning means for assigning a	a constraint assigning means for	
	three-dimensional constraint of motion to the	assigning a three-dimensional constraint of	

the third virtual object to constrain how the	motion to the third virtual object to constrain
third virtual object can rotate with respect to	how the third virtual object can rotate with
the first virtual object; and	respect to the first virtual object.
rendering means for rendering the virtual world	
including the grouped object.	

Regarding claims 102-108, Applicants respectfully request that the Examiner compare claim 102 of this reissue application with claim 1 of the original patent (see table below). Applicants contend that claim 102 is directed to a different invention than claim 1 since claim 102 is directed to program that forms a "hierarchical grouped" object that is represented by a "hierarchical wireframe object" and a "hierarchical polygon" object. Applicants contend that the scope of claims 102-108 are materially different from claim 1, and thus Applicants contend that claims 102-108 do not violate the recapture rule. As noted in *Chisum on Patents*, a patentee may obtain on reissue a claim that varies materially from the claim originally surrendered even though it omits a limitation intentionally added to obtain issuance of the patent.<sup>3</sup>

Claim from original patent (with additions underlined)	Claim in present reissue application (emphasis added)		
1. An apparatus for creating a virtual world	102. (Amended) A computer program		
data base, comprising:	embodied on a computer-readable medium,		
	wherein the computer program is configured to		
	create a data base representing a virtual world		
	by:		
receiving means for receiving first, second and	receiving a plurality of polygon representations		
third polygon representations of respective	of virtual objects;		
first, second and third virtual objects in a			
virtual world;			

<sup>&</sup>lt;sup>3</sup> See Donald S. Chisum, Chisum on Patents §15.03[2][e] (emphasis added).

selecting means, coupled to said receiving	selecting first and second virtual objects from		
means, for selecting a first edge of said first	said plurality of polygon representations of		
virtual object and for selecting a second edge	virtual objects; <sup>4</sup>		
of said second virtual object; and	·		
grouping means, coupled to the receiving	grouping the first and second virtual objects		
means and the selecting means, for grouping	into a hierarchical grouped object, wherein		
said first and second virtual objects in the	said grouping includes:		
virtual world into a grouped object comprising	selecting a first mathematical edge of said first		
said first and second virtual objects joined at	t virtual object;		
an intersection of the first and second edges,	selecting a second mathematical edge of said		
	second virtual object; and		
the grouped object represented by at least one	representing the grouped object by at least one		
of a three-dimensional and rotatable wireframe	of the following:		
object and a three-dimensional and rotatable	a three-dimensional and rotatable		
sweep polygon.	hierarchical wireframe object, and		
	a three-dimensional and rotatable		
	hierarchical polygon object.		

Applicants further highlight that dependent claims 103-108 recited additional features not addressed in claim 1, and thus differ in scope sufficiently to avoid the recapture rule. For example claim 106 recites "assigning a grouping hierarchy...calculating an orientation and position of the child object relative to the first virtual object...assigning an origin on the first virtual object around which the second virtual object can rotate; and assigning a three-dimensional constraint of motion to the second virtual object..."

Regarding claims 10-45 and claims 57-68, Applicants contend that independent claims 10 and 57 contains all of the features germane to the prior art rejection in the original patent under reasoning similar to that highlighted above for claims 46-56 and 69-108.

<sup>&</sup>lt;sup>4</sup> Applicants note that features corresponding to the original "selecting a first edge" and "selecting a second edge" features are recited below (see "grouping").

For at least the reasons set forth above, Applicants contend that claims 1-108 are allowable. Applicants request a telephone conference with the Examiner at the Examiner's convenience to discuss the Examiner's opinion as to what, if any, additional features should be added to the claims outlined above.

## **CONCLUSION**

Applicants submit the application is in condition for allowance, and an early notice to that effect is respectfully requested.

If any extensions of time (under 37 C.F.R. § 1.136) are necessary to prevent the above referenced application(s) from becoming abandoned, Applicant(s) hereby petition for such extensions. If any fees are due, or if any overpayments have been made, the Commissioner is authorized to charge or credit said fees to Conley, Rose, & Tayon, P.C. Deposit Account No. 501505/5181-11402/DRC.

Also enclosed herewith are the following items:

46. (Amended) A memory media comprising program instructions for creating a data base representing a virtual world, wherein the program instructions are executable to implement:

receiving a plurality of polygon representations of <u>a plurality of virtual objects including</u> a first virtual object, a second virtual object, and a third virtual object;

selecting the first and second virtual objects from said plurality of polygon representations of virtual objects using edges of the virtual objects;

grouping the first and second virtual objects into a three-dimensional grouped object represented by at least one of the following:

a three-dimensional and rotatable wireframe object, and

a three-dimensional and rotatable polygon object;

assigning a grouping hierarchy for the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and

calculating an orientation and position of the child object relative to the first virtual object.

20

25

30

69. (Amended) A method for creating a data base representing a virtual world, the method comprising:

receiving a plurality of polygon representations of virtual objects, wherein the plurality of polygon representations include a first, a second, and a third representation of respective first, second, and third virtual objects, wherein the virtual objects have edges;

selecting first and second virtual objects <u>using the edges</u> from said plurality of polygon representations of virtual objects;

grouping the first and second virtual objects into a grouped object comprising a combination of the first and second virtual objects, wherein the first and second virtual objects intersect; and

representing the grouped object by at least one of the following:

a three-dimensional and rotatable wireframe object, and
a three-dimensional and rotatable <a href="mailto:sweep">sweep</a> polygon object.

09/159,509

84. (Amended) A computer program for creating a virtual world data base, wherein said computer program is embodied on computer-readable media and comprises instructions configured to:

[store] <u>read</u> polygon representations of a plurality of virtual objects, <u>including a first virtual</u> object, a second virtual object, and a third virtual object;

select [a] the first virtual object and [a] the second virtual object from said plurality of virtual objects;

assign attributes to the first and second virtual objects;

5

10

15

20

25

30

group said first and second virtual objects into a grouped object, wherein said first and second virtual objects intersect;

represent the grouped object by at least one of the following:

a three-dimensional and rotatable wireframe object, and

a three-dimensional and rotatable polygon object;

assign a grouping hierarchy to the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and calculate an orientation and position of the child object relative to the first virtual object.

97. (Amended) [The] An apparatus [as recited in claim 95,] for creating a virtual world data base, comprising:

<u>a receiving means for receiving first and second polygon representations of respective</u>

<u>first and second virtual objects in a virtual world;</u>

a selecting means coupled to said receiving means and configured to select said first and second virtual objects by selecting one edge from each of said first and second virtual objects;

a grouping means coupled to said receiving means and selecting means, wherein said grouping means is configured to group said first and second virtual objects into a grouped object, wherein the grouped object is represented by at least one of a three-dimensional and rotatable wireframe object and a three dimensional and rotatable polygon object; and

an attribute assigning means coupled to said grouping means, wherein said assigning means is configured to assign an attribute to the first and second virtual objects, wherein the attribute assigning means comprises a hierarchy means for assigning a grouping hierarchy to the first and second virtual objects, wherein the second virtual object is assigned as a child object of

09/159,509

the first virtual object, and wherein an orientation and a position of the child object is calculated relative to the first virtual object, wherein said attribute assigning means further comprises:

an origin assigning means for assigning an origin on the first virtual object around which a third virtual object can rotate, wherein said third virtual object is selected by said selecting means from said plurality of virtual objects; and

a constraint assigning means for assigning a three-dimensional constraint of motion to the third virtual object to constrain how the third virtual object can rotate with respect to the first virtual object.

102. (Amended) A <u>computer program embodied on a computer-readable medium, wherein the computer program is configured to create</u> [method for creating] a data base representing a virtual world [, the method comprising] <u>by</u>:

receiving a plurality of polygon representations of virtual objects;

5

10

15

20

selecting first and second virtual objects from said plurality of polygon representations of virtual objects;

grouping the first and second virtual objects into a hierarchical grouped object, wherein said grouping includes:

selecting a first mathematical edge of said first virtual object; selecting a second mathematical edge of said second virtual object; and representing the grouped object by at least one of the following:

- a three-dimensional and rotatable hierarchical wireframe object, and a three-dimensional and rotatable hierarchical polygon object.
- 103. (Amended) The [method] medium of claim 102, wherein said first and second mathematical edges are single points.
  - 104. (Amended) The [method] <u>medium</u> of claim 102, wherein said first and second mathematical edges are detached from said first and second virtual objects.
- 30 105. (Amended) The [method] medium of claim 102, wherein the first and second virtual objects intersect, and wherein the grouped object comprises said first and second virtual objects

09/159,509

joined with at least a portion of said first edge of said first virtual object contacting at least a portion of said second edge of said second virtual object.

106. (Amended) The [method] medium of claim 102, further comprising:

5

10

15

20

assigning a grouping hierarchy for the first and second virtual objects, wherein the second virtual object is assigned as the child of the first virtual object; and

calculating an orientation and position of the child object relative to the first virtual object.

assigning an origin on the first virtual object around which the second virtual object can rotate; and

assigning a three-dimensional constraint of motion to the second virtual object that constrains how the second virtual object can rotate with respect to the first virtual object.

- 107. (Amended) The [method] <u>medium of</u> [as recited in] claim 102, further comprising specifying a minimum angle and a maximum angle that the second virtual object can rotate with respect to the origin.
- 108. (Amended) The [method] medium of [as recited in] claim 102, further comprising assigning an attributes to the grouped object, wherein the attribute is texture, color, normal direction, maximum rotation angle, or minimum rotation angle.
